Project 1: Bike Store Relational Database Levering Data for Business Insights

Project Summary:

This project focused on analyzing the operations of a bike store chain by leveraging SQL queries on relational data. The business initially relied on multiple CSV files for categories, customers, products, orders, inventory, and staff, which made analysis difficult. The aim was to build a unified relational system, perform structured queries, and generate insights to guide decision-making. The dataset included multiple dimensions—brands, categories, customers, orders, products, staff, stocks, and stores. Using SQL joins, aggregations, filtering, and window functions, the project answered key business questions related to revenue, customer behaviour, inventory, and staff performance.

Strengths:

- 1. **Comprehensive coverage:** Queries addressed all aspects of the business—sales, customers, staff, inventory, and product performance.
- 2. **Actionable insights:** Key outputs like identifying the top 5 best-selling products, most profitable brands, and staff revenue performance can directly inform business strategy.
- 3. **Technical rigor:** Use of SQL joins, aggregation functions, subqueries, and advanced concepts like CTEs and ranking shows strong command of SQL.
- 4. **Scalability potential:** The approach lays the foundation for dashboards, predictive analytics, and integration with visualization tools.

Areas to Improve:

- 1. **Data complexity:** Relationships between tables were challenging, and some queries required debugging. Documenting the schema more clearly could make this easier.
- 2. **Query optimization:** As the dataset grows, performance tuning and indexing will be necessary to handle larger volumes.
- 3. **Visualization:** Results are currently text-based. Incorporating charts or BI dashboards would make insights easier for non-technical stakeholders.
- 4. **Business context:** Some queries provide descriptive outputs but could be extended with predictive or prescriptive analytics (e.g., forecasting future sales, customer segmentation).

Evaluation:

The project successfully demonstrated how SQL can unify and analyze operational data from disparate sources. Key findings included identifying top-selling products, out-of-stock items, high-value customers, and performance rankings of staff and stores. The project proved the importance of structured relational data and showed how SQL can extract deep insights. With further development, the system could evolve into a real-time analytics dashboard for strategic decision-making.

Rating: 8/10

Project 2: Green Destination Employees Attrition Dashboard using Power BI

Project Summary:

The attrition dashboards provide a comprehensive overview of employee turnover within Green Destinations. Using multiple KPIs, charts, and demographic filters, the dashboards highlight critical factors influencing attrition such as job role, years with current manager, education, job satisfaction, salary hikes, and work-life balance. Together, these dashboards help HR teams identify retention challenges and create targeted interventions.

Strengths:

1. **Interactive Filters:** Age, income, gender, job role, years at company, and work-life balance can be adjusted to explore attrition patterns in detail.
2. **Clear KPIs:** Key figures like attrition rate, total attrition count, and employees remaining are clearly displayed.
3. **Visual Variety:** Combination of pie charts, bar graphs, tree maps, scatter plots, and KPIs provides multiple perspectives.
4. **Role and Department Focus:** Dashboards break down attrition not just overall but also by job role, department, and education field.
5. **Trend Analysis:** Years with current manager and years since last promotion reveal how tenure influences attrition risk.

Areas to Improve:

1. **Attrition Rate Clarity:** Dashboard 1 shows attrition rate as 3.20%, while Dashboard 2 shows 16.11%. A unified definition or filter context should be clarified.
2. **Slicer Design:** Some slicers (e.g., “Job Role” and “Department”) could be improved with search functionality to make selection faster.
3. **Drill-down Insights:** More drill-through options (e.g., by location, performance ratings) could provide deeper employee-level understanding.
4. **Benchmarking:** Comparing attrition rates with industry standards would add strategic value.
5. **Predictive View:** Integration of machine learning models to forecast attrition risk could make dashboards more forward-looking.

Evaluation:

The dashboards effectively visualize employee attrition across multiple dimensions, offering HR leaders actionable insights into where turnover is most concentrated. Key drivers include job satisfaction, years with the current manager, and department type. With minor improvements—such as standardizing attrition rate metrics, enabling drill-downs, and adding predictive capabilities—the dashboards can evolve into a powerful decision-support system for workforce planning.

Rating: **7.5/10**
